Abstract

In this paper we study Subquantile Minimization for learning the Huber- ϵ Contamination Problem for Kernel Learning. We assume the adversary has knowledge of the true distribution of \mathcal{P} , and is able to corrupt the covariates and the labels of ϵn samples for $\epsilon \in [0, 0.5)$. The distribution is formed as $\hat{\mathcal{P}} = (1 - \epsilon)\mathcal{P} + \epsilon\mathcal{Q}$, and we want to learn the function $f^* \triangleq \min_{f \in \mathcal{H}} \mathbb{E}_{\mathcal{D} \sim \mathcal{P}} [\mathcal{R}(f; \mathcal{D})]$, from the noisy distribution, $\hat{\mathcal{P}}$. Superquantile objectives have been studied extensively to reduce the risk of the tail [LPMH21, RRM14]. We consider the contrasting case where we want to minimize the body of the risk. We study a gradient-descent approach to solve a variational representation of the Subquantile Objective. Our main algorithmic tool is the *ridge*, which allows us to give a near optimal approximation bound in kernelized ridge regression and kernelized binary cross entropy.

1 Introduction

There has been extensive study of algorithms to learn the target distribution from a Huber ϵ -Contaminated Model for a Generalized Linear Model (GLM), [DKK⁺19, ADKS22, LBSS21, OZS20, FB81] as well as for linear regression [BJKK17, MGJK19]. Robust Statistics has been studied extensively [DK23] for problems such as high-dimensional mean estimation [PBR19, CDGS20] and Robust Covariance Estimation [CDGW19, FWZ18]. Recently, there has been an interest in solving robust machine learning problems by gradient descent [PSBR18, DKK⁺19]. Subquantile minimization aims to address the shortcomings of standard ERM in applications of noisy/corrupted data [KLA18, JZL⁺18]. In many real-world applications, the covariates have a non-linear dependence on labels [AMMIL12, Section 3.4]. In which case it is suitable to transform the covariates to a different space utilizing kernels [HSS08]. Therefore, in this paper we consider the problem of Robust Learning for Kernel Learning.

Definition 1 (Huber ϵ -Contamination Model [HR09]). *Given a corruption parameter $0 < \epsilon < 0.5$, a data matrix, X and labels \mathbf{y} . An adversary is allowed to inspect all samples and modify ϵn samples arbitrarily. The algorithm is then given the ϵ -corrupted data matrix X and ϵ -corrupted labels vector \mathbf{y} as training data.*

Current approaches for robust learning across various machine learning tasks often use gradient descent over a robust objective, [LBSS21]. These robust objectives tend to not be convex and therefore do not have a strong analysis on the error bounds for general classes of models.

We similarly propose a robust objective which has a nonconvex-concave objective. This objective function has also been proposed recently in [HYwL20] where there has been an analysis in the Binary Classification Task. We show Subquantile Minimization reduces to the same objective function given in [HYwL20].

The study of Kernel Learning in the Gaussian Design is quite popular, [CLKZ21, Dic16]. In [CLKZ21], the feature space, $\phi(\mathbf{x}_i) \sim \mathcal{N}(0, \Sigma)$ where Σ is a diagonal matrix of dimension p , where p can be infinite. We will now give our formal definition of the dataset.

Definition 2 (Corruption Model). *Let \mathcal{P} be a distribution over \mathbb{R}^d such that $\mathcal{P}_\# \phi$ is a centered distribution in the Hilbert Space \mathcal{H} with trace-class covariance operator Σ and trace-class sub-Gaussian proxy Γ such that $\Sigma \preceq c\Gamma$. The original dataset is denoted as \hat{P} , the adversary is able to observe \hat{P} and arbitrarily corrupts ϵn samples denoted as Q such that $|Q| = \epsilon n$. The remaining uncorrupted samples are denoted as P such that $|P| = n(1 - \epsilon)$. Together $X \triangleq P \cup Q$ represents the given dataset.*

point to algorithms/more specific results.

Explain the notation for pushforward measure. Explain Gaussian proxy.

Theorem 3. (Informal). *Let the dataset be given as $\{(\mathbf{x}_i, y_i)\}_{i=1}^n$ such that the labels and covariates of ϵn samples arbitrarily corrupted by an adversary. There is an algorithm that, in polynomial time, obtain the following approximation bounds.*

Kernelized Regression:

$$\|f^{(t+1)} - f^*\|_{\mathcal{H}} \leq \epsilon + O\left(\left((Q_k \vee \|\Gamma\|_{\text{op}}) \|\Gamma\|_{\text{op}}\right)^{-1} \left(\sigma + \frac{\sigma}{\sqrt{n(1-\epsilon)}} + \frac{C\|f^*\|_{\mathcal{H}}}{n(1-\epsilon)}\right)\right)$$

Kernel Binary Classification:

$$\|f^{(T)} - f^*\|_{\mathcal{H}} \leq \epsilon + O\left(\sqrt{\frac{\mathcal{E}_{\text{OPT}}}{n(1-\epsilon)Q_m}}\right) + O\left(\frac{\sqrt{Q_k}\|f^*\|_{\mathcal{H}}}{\sqrt{Q_m}n(1-\epsilon)}\right)$$

1.1 Contributions

Our main contribution is the approximation bounds for Subquantile Minimization in kernelized ridge regression and kernelized binary classification with binary cross entropy loss described in Algorithms ?? and ??, respectively. Our proof techniques extend [BJK15, ADKS22] as we do not assume the covariates follow the spherical Gaussian property, as such a property will not hold for any infinite-dimensional Hilbert Space.

2 Preliminaries

Notation. We denote $[T]$ as the set $\{1, 2, \dots, T\}$. We define $(x)^+ \triangleq \max(0, x)$ as the Rectified Linear Unit (ReLU) function. We say $y = O(x)$ if there exists x_0 s.t. for all $x \geq x_0$ there exists C s.t. $y \leq Cx$. We denote \tilde{O} to ignore log factors. We say $y = \Omega(x)$ if there exists x_0 s.t. for all $x \geq x_0$ there exists C s.t. $y \geq Cx$. We denote $a \vee b \triangleq \max(a, b)$ and $a \wedge b \triangleq \min(a, b)$. We define \mathbb{S}^{d-1} as the sphere $\{\mathbf{x} \in \mathbb{R}^d : \|\mathbf{x}\| = 1\}$.

2.1 Reproducing Kernel Hilbert Spaces

Let the function $\phi : \mathbb{R}^d \rightarrow \mathcal{H}$ represent the Hilbert Space Representation or ‘feature transform’ from a vector in the original covariate space to the RKHS. We define $k : \mathbb{R}^d \times \mathbb{R}^d \rightarrow \mathbb{R}$ as $k(\mathbf{x}, \mathbf{x}) \triangleq \langle \phi(\mathbf{x}), \phi(\mathbf{x}) \rangle_{\mathcal{H}}$. For a function in a RKHS, $f \in \mathcal{H}$, it follows for a function f parameterized by weights $\mathbf{w} \in \mathbb{R}^n$, that the point evaluation function is given as $f : \mathbb{R}^d \rightarrow \mathbb{R}$ and defined $f(\cdot) \triangleq \sum_{i \in [n]} w_i k(\mathbf{x}_i, \cdot)$.

$$f(\mathbf{x}) = \langle f, k(\mathbf{x}, \cdot) \rangle_{\mathcal{H}} = \langle f, \phi(\mathbf{x}) \rangle_{\mathcal{H}}, \quad \forall f \in \mathcal{H}$$

The norm is given as $\|f\|_{\mathcal{H}} = \sqrt{\langle f, f \rangle_{\mathcal{H}}}$.

2.2 Tensor Products

Let \mathcal{H}, \mathcal{K} be Hilbert Spaces, then $\mathcal{H} \otimes \mathcal{K}$ is the tensor product space and is also a Hilbert Space [RaR02]. For $\phi_1, \psi_1 \in \mathcal{H}$ and $\phi_2, \psi_2 \in \mathcal{K}$, the inner product is defined as $\langle \phi_1 \otimes \phi_2, \psi_1 \otimes \psi_2 \rangle_{\mathcal{H} \otimes \mathcal{K}} = \langle \phi_1, \psi_1 \rangle_{\mathcal{H}} \langle \phi_2, \psi_2 \rangle_{\mathcal{K}}$. We will utilize tensor products when we discuss infinite dimensional covariance estimation.

2.3 Sub-Gaussian Random Functions in the Hilbert Space

In this paper we sample the target covariates $\mathbf{x} \sim \mathcal{X}$ such that $\phi(\mathbf{x}) \triangleq X \sim \mathcal{P}_{\#} \phi$ is sub-Gaussian in the Hilbert Space where $\mathbf{E}[X] = \mathbf{0}$ and covariance $\mathbf{E}[X \otimes X] = \Sigma$ with proxy Γ , where $\Sigma \preceq 4 \|X\|_{\psi_2}^2 \Gamma$, where we denote \preceq as the Löwner order. We have X is a centered Hilbert Space sub-Gaussian random function if for all $\theta > 0$,

$$\mathbf{E}_{X \sim \mathcal{P}} [\exp(\theta \langle X, v \rangle_{\mathcal{H}})] \leq \exp\left(\frac{\alpha^2 \theta^2 \langle v, \Gamma v \rangle_{\mathcal{H}}}{2}\right) \quad (1)$$

where the sub-Gaussian Norm for a centered Hilbert Space Function is given as

$$\|X\|_{\psi_2} \triangleq \inf \left\{ \alpha \geq 0 : \mathbf{E} \left[e^{\langle v, X \rangle_{\mathcal{H}}} \right] \leq e^{\alpha^2 \langle v, \Gamma v \rangle_{\mathcal{H}} / 2} : \forall v \in \mathcal{H} \right\}$$

Then we say $X \sim \mathcal{SG}(\Gamma, \alpha)$, where if $\alpha = 1$, we will say $X \sim \mathcal{SG}(\Gamma)$. The Gaussian Design for the Feature Space has gained popularity in the study of kernel learning [CLKZ21]. The sub-Gaussian design is the standard assumed distribution in the robust statistics literature, [JLT20, ADKS22], and has been studied extensively in the context of iterative thresholding algorithms for linear regression.

2.4 Assumptions

We will first give our assumptions for robust kernelized regression.

Assumption 4 (Sub-Gaussian Design). *We assume for $\mathbf{x}_i \sim \mathcal{X}$, then it follows for the function to the Hilbert Space, $\phi(\cdot) : \mathcal{X} \rightarrow \mathcal{H}$,*

$$\phi(\mathbf{x}) \triangleq X \sim \mathcal{P}_{\#} \phi \triangleq \mathcal{SG}(\Gamma, 1/2)$$

where Γ is a possibly infinite dimensional covariance operator.

Assumption 5 (Bounded Functions). *We assume for $\mathbf{x}_i \sim \mathcal{P} \in \mathcal{X}$, then it follows for the feature map, $\phi(\cdot) : \mathcal{X} \rightarrow \mathcal{H}$,*

$$\sup_{\mathbf{x} \in \mathcal{X}} \|\phi(\mathbf{x})\|_{\mathcal{H}}^2 \leq P_k < \infty$$

where \mathcal{H} is a Reproducing Kernel Hilbert Space.

Assumption 6 (Normal Residuals). *Let $\inf_{f \in \mathcal{H}} \mathbf{E}_{(\mathbf{x}, y) \sim \mathcal{D}} [\mathcal{R}(f; \mathbf{x}, y)]$. The residual is defined as $\mu_i \triangleq f^*(\mathbf{x}_i) - y_i$. Then we assume for some $\sigma > 0$, it follows*

$$\mu_i \sim \mathcal{N}(0, \sigma^2)$$

2.5 Related Work

The idea of iterative thresholding algorithms for robust learning tasks dates back to 1806 by Legendre [Leg06]. Iterative thresholding have been studied theoretically and tested empirically in various machine learning domains [HYW⁺23, MGJK19]. Therefore, we will dedicate this subsection to reviewing such works and to make clear our contributions to the iterative thresholding literature.

[BJK15] study iterative thresholding for least squares regression / sparse recovery. In particular, one part of their study is of a gradient descent algorithm when the data $\mathcal{P} = \mathcal{Q} = \mathcal{N}(\mathbf{0}, \mathbf{I})$ or multivariate sub-Gaussian with proxy \mathbf{I} . Their approximation bounds relies on the fact that $\lambda_{\min}(\Sigma) = \lambda_{\max}(\Sigma)$ and with sufficiently large data and sufficiently small ϵ , $\lambda_{\max}(\mathbf{X})/\lambda_{\min}(\mathbf{X}) \searrow 1$. This is similar to the study by [ADKS22], where the iterative trimmed maximum likelihood estimator is studied for General Linear Models. The algorithm studied by [ADKS22] utilizes a filtering algorithm with the sketching matrix $\Sigma^{-1/2}$ so the columns of \mathbf{X} are sampled from a multivariate sub-Gaussian Distribution with proxy \mathbf{I} before running the iterative thresholding procedure. This ‘whitening’ procedure to decrease the conditioning number of the covariates is also done in recent work, [SBRJ19, BJKK17].

Conditioning covariates does not generalize to kernel learning where we are given a matrix \mathbf{K} which is equivalent to inner product of the quasimatrix¹, Φ , with itself. In the infinite dimensional case, it is not possible to sketch the kernel matrix [W⁺14] in order to have the original covariates be well-conditioned. In the finite dimensional case, the feature maps can be quite large and it is very difficult to obtain in practice. Thus, we are left with Φ where the columns are sampled from a sub-Gaussian Distribution with proxy Γ is a trace-class operator, which implies the eigenvalues tend to zero, i.e. $\lambda_{\inf}(\Gamma) = 0$, and there is no longer a notion of $\lambda_{\min}(\Gamma)$.

3 Subquantile Minimization

We propose to optimize over the subquantile of the risk. The p -quantile of a random variable, U , is given as $\mathcal{Q}_p(U)$, this is the largest number, t , such that the probability of $U \leq t$ is at least p .

$$\mathcal{Q}_p(U) \leq t \iff \mathbf{Pr}\{U \leq t\} \geq p$$

The p -subquantile of the risk is then given by

$$\mathbf{L}_p(U) = \frac{1}{p} \int_0^p \mathcal{Q}_p(U) dq = \mathbf{E}[U | U \leq \mathcal{Q}_p(U)] = \max_{t \in \mathbb{R}} \left\{ t - \frac{1}{p} \mathbf{E}(t - U)^+ \right\}$$

Given an objective function, \mathcal{R} , the kernelized learning problem becomes:

$$\min_{f \in \mathcal{K}} \max_{t \in \mathbb{R}} \left\{ g(t, f) \triangleq t - \sum_{i=1}^n (t - \mathcal{R}(f; \mathbf{x}_i, y_i))^+ \right\}$$

where t is the p -quantile of the empirical risk. Note that for a fixed t therefore the objective is not concave with respect to \mathbf{w} . Thus, to solve this problem we use the iterations from Equation 11 in [RHL⁺20]. Let $\text{Proj}_{\mathcal{K}}$ be the projection of a function on to the convex set $\mathcal{K} \triangleq \{f \in \mathcal{H} : \|f\|_{\mathcal{H}} \leq R\}$, then our update steps are

$$\begin{aligned} t^{(k+1)} &= \arg \max_{t \in \mathbb{R}} g(f^{(k)}, t) \\ f^{(k+1)} &= \text{Proj}_{\mathcal{K}} \left[f^{(k)} - \eta \nabla_f g(f^{(k)}, t^{(k+1)}) \right] \end{aligned}$$

The proof of convergence for the above algorithm was given in [JNJ20][Theorem 35]. The sufficient condition for convergence is $g(f, t)$ is concave with respect to t , which for the subquantile objective is simple to show.

¹A quasimatrix is an infinite-dimensional analogue of a tall-skinny matrix that represents an ordered set of functions in ℓ_2 (see e.g. [TT15]).

3.1 Reduction to Iterative Thresholding

To consider theoretical guarantees of Subquantile Minimization, we first analyze the inner and outer optimization problems. We first analyze kernel learning in the presence of corrupted data. Next, we provide error bounds for the two most important kernel learning problems, kernel ridge regression, and kernel classification. Now we will give our first result regarding kernel learning in the Huber ϵ -contamination model. Now we will analyze the two-step minimax optimization steps described in Section 3.

Lemma 7. *Let $\mathcal{R} : \mathcal{H} \times \mathbb{R} \rightarrow \mathbb{R}$ be a loss function (not necessarily convex). Let $\mathbf{x}_{[i]}$ represent the point with the i -th smallest loss w.r.t \mathcal{R} . If we denote $\hat{\nu}_i \triangleq \mathcal{R}(f; \mathbf{x}_{[i]}, y_{[i]})$, it then follows $\hat{\nu}_{n(1-\epsilon)} \in \arg \max_{t \in \mathbb{R}} g(t, f)$.*

Proof. First we can note, the max value of t for g is equivalent to the min value of t for the convex w.r.t t function $-g$. We can now find the Fermat Optimality Conditions for g .

$$\partial(-g(t, f)) = \partial \left(-t + \frac{1}{n(1-\epsilon)} \sum_{i=1}^n (t - \hat{\nu}_i)^+ \right) = -1 + \frac{1}{n(1-\epsilon)} \sum_{i=1}^{n(1-\epsilon)} \begin{cases} 1 & \text{if } t > \hat{\nu}_i \\ 0 & \text{if } t < \hat{\nu}_i \\ [0, 1] & \text{if } t = \hat{\nu}_i \end{cases}$$

We observe when setting $t = \hat{\nu}_{n(1-\epsilon)}$, it follows that $0 \in \partial(-g(t, f))$. This is equivalent to the $(1-\epsilon)$ -quantile of the Empirical Risk. \blacksquare

From Lemma 7, we see that t will be greater than or equal to the errors of exactly $n(1-\epsilon)$ points. Thus, we are continuously updating over the $n(1-\epsilon)$ minimum errors.

Lemma 8. *Let $\hat{\nu}_i \triangleq \mathcal{R}(f; \mathbf{x}_{[i]}, y_{[i]})$, if we choose $t^{(k+1)} = \hat{\nu}_{n(1-\epsilon)}$ as by Lemma 7, it then follows $\nabla_f g(t^{(k)}, f^{(k)}) = \frac{1}{n(1-\epsilon)} \sum_{i=1}^{n(1-\epsilon)} \nabla_f \mathcal{R}(f^{(k)}; \mathbf{x}_{[i]}, y_{[i]})$.*

Proof. By our choice of $t^{(k+1)}$, it follows,

$$\begin{aligned} \partial_f g(t^{(k+1)}, f^{(k)}) &= \partial_f \left(t^{(k+1)} - \frac{1}{n(1-\epsilon)} \sum_{i=1}^n \left(t^{(k+1)} - \mathcal{R}(f^{(k)}; \mathbf{x}_{[i]}, y_{[i]}) \right)^+ \right) \\ &= -\frac{1}{n(1-\epsilon)} \sum_{i=1}^{n(1-\epsilon)} \partial_f \left(t^{(k+1)} - \mathcal{R}(f^{(k)}; \mathbf{x}_{[i]}, y_{[i]}) \right)^+ \\ &= \frac{1}{n(1-\epsilon)} \sum_{i=1}^n \nabla_f \mathcal{R}(f^{(k)}; \mathbf{x}_{[i]}, y_{[i]}) \begin{cases} 1 & \text{if } t > \hat{\nu}_i \\ 0 & \text{if } t < \hat{\nu}_i \\ [0, 1] & \text{if } t = \hat{\nu}_i \end{cases} \end{aligned}$$

Now we note $\hat{\nu}_{n(1-\epsilon)} \leq t^{(k+1)} \leq \hat{\nu}_{n(1-\epsilon)+1}$. Then, we have

$$\partial_f g(t^{(k+1)}, f^{(k)}) \ni \frac{1}{n(1-\epsilon)} \sum_{i=1}^{n(1-\epsilon)} \nabla_f \mathcal{R}(f^{(k)}; \mathbf{x}_{[i]}, y_{[i]})$$

This concludes the proof. \blacksquare

We have therefore shown that the two-step optimization of Subquantile Minimization gives the iterative thresholding algorithm.

4 Convergence

In this section we give the algorithm for subquantile minimization for both kernelized ridge regression and kernelized binary classification. Then we give our convergence results.

4.1 Kernelized Ridge Regression

The loss for the Kernel Ridge Regression problem for a single training pair $(\mathbf{x}_i, y_i) \in \mathcal{D}$ is given by the following equation

$$\mathcal{R}(f; \mathbf{x}_i, y_i) = (f(\mathbf{x}_i) - y_i)^2 + \tau \|f\|_{\mathcal{H}}^2$$

Our goals throughout the proofs will be to obtain approximation bounds for infinite-dimensional kernels. The key challenge is the obvious undetermined problem, i.e. considering an infinite eigenfunction basis, we require infinite samples to obtain an accurate approximation. We will now give the algorithm.

Algorithm 1 (Subquantile Minimization for Kernelized Ridge Regression and Binary Classification by Gradient Descent).

Input: Data Matrix: $\mathbf{X} \in \mathbb{R}^{n \times d}$, $n \gg d$; Labels: $\mathbf{y} \in \mathbb{R}^n$

1. Calculate the Kernel Matrix, $\mathbf{K}_{ij} \triangleq k(\mathbf{x}_i, \mathbf{x}_j)$.
2. Set the number of iterations

$$T = O\left(n(1 - \epsilon) \log\left(\frac{\|f^*\|_{\mathcal{H}}}{\epsilon}\right)\right)$$

3. **for** $k = 1, 2, \dots, T$ **do**

4. Find the Subquantile denoted as $\mathbf{S}^{(k)}$ as the set of $(1 - \epsilon)n$ elements with the lowest error with respect to the loss function.
5. Calculate the gradient update.

$$\nabla_f g(t^{(k+1)}, f^{(k)}) \leftarrow \frac{2}{n(1 - \epsilon)} \sum_{i \in \mathbf{S}^{(k)}} (f^{(k)}(\mathbf{x}_i) - y_i) \cdot \phi(\mathbf{x}_i) + \tau f^{(t)} \quad (\text{Regression})$$

$$\nabla_f g(t^{(k+1)}, f^{(k)}) \leftarrow \frac{1}{n(1 - \epsilon)} \sum_{i \in \mathbf{S}^{(k)}} (\sigma(f^{(k)}(\mathbf{x}_i)) - y_i) \cdot \phi(\mathbf{x}_i) + \tau f^{(t)} \quad (\text{Classification})$$

6. Perform Gradient Descent Iteration.

$$f^{(k+1)} \leftarrow f^{(k)} - \eta \nabla g(f^{(k)}, t^{(k+1)})$$

Return: Function in \mathcal{H} : $f^{(T)}$

Algorithm 2 (Subquantile Minimization for Kernelized Regression with Full Solves).

Input: Data Matrix: $\mathbf{X} \in \mathbb{R}^{n \times d}$; Labels: $\mathbf{y} \in \mathbb{R}^n$

1. Calculate the kernel matrix, $\mathbf{K}_{ij} \triangleq k(\mathbf{x}_i, \mathbf{x}_j)$.
2. Set the number of iterations

$$T = O\left(n \log\left(\frac{\|f^*\|_{\mathcal{H}}}{\epsilon}\right)\right)$$

3. **for** $k = 1, 2, \dots, T$ **do**

4. Find the Subquantile denoted as $\mathbf{S}^{(k)}$ as the set of $(1 - \epsilon)n$ elements with the lowest error with respect to the loss function.
5. Solve the sub-problem

$$f^{(k)} \leftarrow \Phi_{\mathbf{S}^{(k)}} (\mathbf{K}_{\mathbf{S}^{(k)}} + n(1 - \epsilon)\lambda \mathbf{I})^{-1} \mathbf{y}_{\mathbf{S}^{(k)}}$$

Return: Function in \mathcal{H} : $f^{(T)}$

Theorem 9 (Subquantile Minimization for Overparameterized Regression). *Algorithm 1 run on a dataset $\mathcal{D} \sim \hat{\mathcal{P}}$ such that $\mathbf{X} \in \mathbb{R}^{p \times n}$ where $p \geq n$ and return $\hat{\mathbf{w}}$. Then, with probability exceeding $1 - \delta$, when $n \geq O(f(\Gamma))$, then*

$$\|\mathbf{w}^{(T)} - \mathbf{w}^*\|_2 \leq \varepsilon + O(\Xi)$$

after $T = O\left(\log\left(\frac{\|\mathbf{w}^*\|}{\varepsilon}\right)\right)$ iterations.

Theorem 10 (Subquantile Minimization for Kernelized Regression). *Algorithm 1 run on a dataset $\mathcal{D} \sim \hat{\mathcal{P}}$ and return \hat{f} . Then with probability exceeding $1 - \delta$ and when $n \geq (1 - \epsilon)^{-1} \left(256 + 64(P_k/\lambda_{\min}(\Gamma))^2 \log(2/\delta)\right)$ and $\epsilon \leq \frac{1}{32} \left(\frac{\lambda_{\min}(\Gamma)}{P_k}\right)^2$,*

$$\|f^{(T)} - f^*\|_{\mathcal{H}} \leq \varepsilon + \frac{2\sigma}{3\|\Gamma\|_{\text{op}}} + \frac{2\sqrt{(1 - \epsilon)}\|f^*\|_{\mathcal{H}}}{3\epsilon\sqrt{n}Q_k} + \frac{20}{3} \left(\frac{\epsilon}{1 - 2\epsilon}\right) \frac{\sqrt{\lambda_{\max}(\Gamma)Q_k}}{\lambda_{\min}(\Gamma)} \|f^*\|_{\mathcal{H}}$$

after $T = O\left(\frac{\epsilon}{1 - \epsilon} \log\left(\frac{\|f^*\|_{\mathcal{H}}}{\varepsilon}\right)\right)$ iterations.

Runtime. The calculation of the Kernel Matrix, \mathbf{K} , can be done in $O(n^2)$. To find $t^{(k+1)}$, we first must calculate the errors of all the elements, which is given by $\boldsymbol{\xi}^{(t)} \triangleq \mathbf{K}\mathbf{w}^{(t)} - \mathbf{y}$, considering $\mathbf{K} \in \mathbb{R}^{n \times n}$ and $\mathbf{w}^{(t)} \in \mathbb{R}^n$, this is a $O(n^2)$ calculation. Then to find the $n(1 - \epsilon)$ -th largest element, we can run a selection algorithm in worst-case time $O(n \log n)$. Calculating the gradient and updating the function is a $O(n^2)$ time step due to the matrix-vector multiplication. Then considering the choice of T , we have the algorithm runs in time $O\left(n^2 \log\left(\frac{\|f^*\|_{\mathcal{H}}}{\varepsilon}\right)\right)$.

Theorem 11 (Subquantile Minimization for Kernelized Regression with Full Solves). *Suppose $\phi(\mathbf{x}_i) \triangleq X_i \in \mathcal{H}$ such that \mathcal{H} is of finite rank. Then there exists an algorithm such that with probability exceeding $1 - \delta$ and when $n \geq \Xi$ and $\epsilon \leq \Xi$,*

$$\|f^{(T)} - f^*\|_{\mathcal{H}} \leq \varepsilon + O(\Xi)$$

after $T = O\left(\log\left(\frac{\Xi}{\varepsilon}\right)\right)$ iterations.

Theorem 12 (Subquantile Minimization for Over-Parameterized Regression with Full Solves). *Suppose $\mathbf{x}_i \in \mathcal{R}^p$ such that n . Then there exists an algorithm such that with probability exceeding $1 - \delta$,*

$$\|\mathbf{w}^{(T)} - \mathbf{w}^*\|_2 \leq \varepsilon + O(\Xi)$$

after $T = O\left(\log\left(\frac{\Xi}{\varepsilon}\right)\right)$ iterations.

The full proof of Theorem 10 with explicit constants is given in ???. A direct application of Theorem 10 is that learning an infinite dimensional function f^* to within ε error in the Hilbert Space Norm requires infinite data. Furthermore, we see that given covariate noise and label noise, our bound requires more iterations dependent on the magnitude of the corruption. Such a result is corroborated in [SST⁺18].

4.2 Kernelized Binary Classification

The Negative Log Likelihood for the the Kernel Classification problem is given by the following equation for a single training pair $(\mathbf{x}_i, y_i) \sim \mathcal{D}$.

$$\mathcal{R}(f; \mathbf{x}_i, y_i) = -\mathbb{I}\{y_i = 1\} \log(\sigma(f(\mathbf{x}_i))) - \mathbb{I}\{y_i = 0\} \log(1 - \sigma(f(\mathbf{x}_i)))$$

Theorem 13 (Subquantile Minimization for Binary Classification is Good with High Probability). *Let Algorithm alg:subq-kernel be run on a dataset $\mathcal{D} \sim \hat{\mathcal{P}}$ with learning rate $\eta \triangleq \Omega(\ell^{-1})$. Then after $O\left(n \log\left(\frac{\|f^*\|_{\mathcal{H}}}{\varepsilon}\right)\right)$ gradient descent iterations, with probability exceeding $1 - \delta$ and a positive constant C ,*

$$\|f^{(T)} - f^*\|_{\mathcal{H}} \leq \varepsilon + O\left(\sqrt{\frac{\mathcal{E}_{\text{OPT}}}{n(1 - \epsilon)Q_m}}\right) + O\left(\frac{\sqrt{Q_k}\|f^*\|_{\mathcal{H}}}{\sqrt{Q_m n(1 - \epsilon)}}\right)$$

for $n \geq (1 - \epsilon)^{-1} \left(16\|\Gamma\|_{\text{op}}^2 + 2P_k^2 \log(2/\delta)\right)$.

Proof. The proof is deferred to ??.

Theorem 14 (Subquantile Minimization for Generalized Linear Models is Good with High Probability). *Let Algorithm 1 be run on a dataset $\mathcal{D} \sim \hat{\mathcal{P}}$ with learning rate $\eta \triangleq \Omega(\ell^{-1})$ and link function $\omega : \mathbb{R} \rightarrow \mathbb{R}$, s.t. $C_1 \leq \omega'(x) \leq C_2$ for absolute constants $C_1, C_2 > 0$. Then after $O\left(n \log\left(\frac{\|f^*\|_{\mathcal{H}}}{\varepsilon}\right)\right)$ gradient descent iterations, with probability exceeding $1 - \delta$ and a positive constant C ,*

$$\|f^{(T)} - f^*\|_{\mathcal{H}} \leq \varepsilon$$

for $n \geq (1 - \epsilon)^{-1} \left(16 \|\Gamma\|_{\text{op}}^2 + 2P_k^2 \log(2/\delta)\right)$.

Proof. The proof is deferred to § D.1.

5 Discussion

The main contribution of this paper is the study of a nonconvex-concave formulation of Subquantile minimization for the robust learning problem for kernel ridge regression and kernel classification. We present an algorithm to solve the nonconvex-concave formulation and prove rigorous error bounds which show that the more good data that is given decreases the error bounds.

Extension to Finite Dimensional Kernels. When considering finite dimensional kernels we no longer require the Ridge.

Theory. We develop strong theoretical bounds on the normed difference between the function returned by Subquantile Minimization and the optimal function for data in the target distribution, \mathcal{P} , in the sub-Gaussian Design. We are able to show if the number of inliers is sufficiently small, then the kernelized binary classification problem with binary cross-entropy loss is consistent.

Future Work. The analysis of Subquantile Minimization can be extended to neural networks as kernel learning can be seen as a one-layer network. This generalization will be appear in subsequent work. Another interesting direction work in optimization is for accelerated methods for optimizing non-convex concave min-max problems with a maximization oracle. The current theory analyzes standard gradient descent for the minimization. Ideas such as Momentum and Nesterov Acceleration in conjunction with the maximum oracle are interesting and can be analyzed in future work.

A Probability Theory

In this section we will give various concentration inequalities on the inlier data for functions in the Reproducing Kernel Hilbert Space.

A.1 Finite Dimensional Concentrations of Measure

Proposition 15. *Let $\mu_1, \dots, \mu_n \sim \mathcal{N}(0, \sigma^2)$ for some $\sigma > 0$, then it follows for any $C \geq 1$,*

$$\Pr \left\{ \sum_{i=1}^n \mu_i^2 \geq Cn\sigma^2 \right\} \leq \exp(-(n/2)(C - 1 + \ln(1/C)))$$

Proof. Concatenate all the samples μ_i into a vector $\boldsymbol{\mu} \in \mathbb{R}^n$.

$$\begin{aligned} \Pr_{\boldsymbol{\mu} \sim \mathcal{N}(\mathbf{0}, \sigma^2 \mathbf{I})} \left\{ \|\boldsymbol{\mu}\|^2 \geq t \right\} &\leq \inf_{\theta > 0} \mathbf{E}_{\boldsymbol{\mu} \sim \mathcal{N}(\mathbf{0}, \sigma^2 \mathbf{I})} \left[\exp \left(\theta \sum_{i=1}^n \mu_i^2 \right) \right] \exp(-\theta t) \\ &= \inf_{\theta > 0} \prod_{i=1}^n \mathbf{E}_{\mu_i \sim \mathcal{N}(0, \sigma^2)} [\exp(\theta \mu_i^2)] \exp(-\theta t) \leq \inf_{0 < \theta < (1/2)\sigma^{-2}} \prod_{i=1}^n \frac{1}{\sqrt{1 - 2\theta\sigma^2}} \exp(-\theta t) \\ &= \inf_{0 < \theta < (1/2)\sigma^{-2}} \exp(-(\theta t + (n/2) \ln(1 - 2\theta\sigma^2))) \\ &= \exp(-(t/2\sigma^2) - (n/2) + (n/2) \ln(n\sigma^2/t)) \\ &= \exp(-(n/2)(C - 1 + \ln(1/C))) \end{aligned}$$

In the second inequality we utilize the MGF for a non-standard χ^2 variable. In the final equality we substitute in $t \triangleq Cn\sigma^2$. ■

A.2 Hilbert Space Concentrations of Measure

Fact 16 (Sum of Binomial Coefficients [CLRS22]). *Let $k, n \in \mathbb{N}$ such that $k \leq n$, then*

$$\sum_{i=0}^k \binom{n}{i} \leq \left(\frac{en}{k} \right)^k$$

Proposition 17 (Jensen's Inequality [Jen06]). *Suppose φ is a convex function, then for a random variable X , it holds*

$$\varphi(\mathbf{E}[X]) \leq \mathbf{E}[\varphi(X)]$$

The inequality is reversed for φ concave.

We will now study the covariance approximation problem. Our main probabilistic tool will be McDiarmid's Inequality.

Proposition 18 (McDiarmid's Inequality [M⁺89]). *Suppose $f : \mathcal{X}_1 \times \dots \times \mathcal{X}_n \rightarrow \mathbb{R}$. Consider i.i.d X_1, \dots, X_n where $X_i \in \mathcal{X}_i$ for all $i \in [n]$. If there exists constants c_1, \dots, c_n , such that for all $x_i \in \mathcal{X}_i$ for all $i \in [n]$, it holds*

$$\sup_{\tilde{X}_i \in \mathcal{X}_i} |f(X_1, \dots, X_{i-1}, X_i, X_{i+1}, \dots, X_n) - f(X_1, \dots, X_{i-1}, \tilde{X}_i, X_{i+1}, \dots, X_n)| \leq c_i$$

Then for any $t > 0$, it holds

$$\Pr \{ f(X_1, \dots, X_n) - \mathbf{E}[f(X_1, \dots, X_n)] \geq t \} \leq \exp \left(-\frac{2t^2}{\sum_{i=1}^n c_i^2} \right)$$

Theorem 19 (Mean Estimation in the Hilbert Space [TSM⁺17]). *Define $P_n \triangleq \frac{1}{n} \sum_{i=1}^n \delta_{X_i}$ and P be the distribution of the covariates in \mathcal{X} . Suppose $r : \mathcal{X} \rightarrow \mathcal{H}$ is a continuous function such that $\sup_{X \in \mathcal{X}} \|r(X)\|_{\mathcal{H}}^2 \leq C_k < \infty$. Then with probability at least $1 - \delta$,*

$$\left\| \int_{\mathcal{X}} r(x) dP_n(x) - \int_{\mathcal{X}} r(x) dP(x) \right\| \leq \sqrt{\frac{C_k}{n}} + \sqrt{\frac{2C_k \log(1/\delta)}{n}}$$

We will strengthen upon the result by [TSM⁺17] by using knowledge of the distribution to first derive the expectation.

Proposition 20 (Probabilistic Bound on Infinite Dimensional Covariance Estimation). *Let $\mathbf{x}_1, \dots, \mathbf{x}_n$ be i.i.d sampled from \mathcal{P} such that $\phi(\mathbf{x}_i) \triangleq X_i \sim \mathcal{P}_\# \phi$ (Assumption 4). Denote \mathcal{S} as all subsets of $[n]$ with size from $n(1-2\epsilon)$ to $(1-\epsilon)n$. We then have simultaneously with probability exceeding $1-\delta$,*

$$\begin{aligned} \left\| \frac{1}{n} \sum_{i=1}^n X_i \otimes X_i - \Sigma \right\|_{\text{HS}} &\leq \sqrt{\frac{8}{n}} \|\Gamma\|_{\text{op}} + \sqrt{\frac{2 \log(2/\delta)}{n}} P_k \\ \max_{A \in \mathcal{S}} \left\| \frac{1}{(1-\epsilon)n} \sum_{i \in A} X_i \otimes X_i - \Sigma \right\|_{\text{HS}} &\leq \sqrt{\frac{8}{(1-\epsilon)n}} \|\Gamma\|_{\text{op}} + \sqrt{\frac{2P_k^2 \log(2/\delta)}{(1-\epsilon)n}} + P_k \sqrt{\frac{\epsilon \log \epsilon^{-1}}{(1-\epsilon)}} \end{aligned}$$

Proof. We will calculate the mean operator in the Hilbert Space $\mathcal{H} \otimes \mathcal{H}$ and use the \sqrt{n} -consistency of estimating the mean-element in a Hilbert Space to obtain the probability bounds.

$$\begin{aligned} \mathbf{E}_{X_i \sim \mathcal{P}_\# \phi} \left\| \frac{1}{(1-\epsilon)n} \sum_{i=1}^{(1-\epsilon)n} X_i \otimes X_i - \Sigma \right\|_{\text{HS}} &\stackrel{(ii)}{\leq} \mathbf{E}_{X_i \sim \mathcal{P}_\# \phi} \mathbf{E}_{\tilde{X}_i \sim \mathcal{P}_\# \phi} \left\| \frac{1}{(1-\epsilon)n} \sum_{i=1}^{(1-\epsilon)n} X_i \otimes X_i - \tilde{X}_i \otimes \tilde{X}_i \right\|_{\text{HS}} \\ &\stackrel{(iii)}{=} \mathbf{E}_{X_i \sim \mathcal{P}_\# \phi} \mathbf{E}_{\tilde{X}_i \sim \mathcal{P}_\# \phi} \mathbf{E}_{\xi_i \sim \mathcal{R}} \left\| \frac{1}{(1-\epsilon)n} \sum_{i=1}^{(1-\epsilon)n} \xi_i (X_i \otimes X_i - \tilde{X}_i \otimes \tilde{X}_i) \right\|_{\text{HS}} \\ &\leq \mathbf{E}_{X_i \sim \mathcal{P}_\# \phi} \mathbf{E}_{\xi_i \sim \mathcal{R}} \left\| \frac{2}{(1-\epsilon)n} \sum_{i=1}^{(1-\epsilon)n} \xi_i (X_i \otimes X_i) \right\|_{\text{HS}} \\ &\leq \frac{2}{(1-\epsilon)n} \mathbf{E}_{X_i \sim \mathcal{P}_\# \phi} \left(\mathbf{E}_{\xi_i \sim \mathcal{R}} \left\| \sum_{i=1}^{(1-\epsilon)n} \xi_i (X_i \otimes X_i) \right\|_{\text{HS}}^2 \right)^{1/2} \end{aligned}$$

In (ii) we note that $X_i \otimes X_i - \Gamma$ is a mean $\mathbf{0}$ operator in the tensor product space $\mathcal{H} \otimes \mathcal{H}$. Then for $X, Y \in \mathcal{H} \otimes \mathcal{H}$ s.t. $\mathbf{E}[Y] = \mathbf{0}$ it follows $\|X\|_{\text{HS}} = \|X - \mathbf{E}[Y]\|_{\text{HS}} = \|\mathbf{E}[X - Y]\|_{\text{HS}}$ and finally we apply Jensen's Inequality. Let e_k for $k \in [p]$ (p possibly infinite) represent a complete orthonormal basis for the image of Γ . By expanding out the Hilbert-Schmidt Norm, we then have

$$\begin{aligned} &\frac{2}{(1-\epsilon)n} \left(\mathbf{E}_{X_i \sim \mathcal{P}_\# \phi} \mathbf{E}_{\xi_i \sim \mathcal{R}} \left\| \sum_{i=1}^{(1-\epsilon)n} \xi_i (X_i \otimes X_i) \right\|_{\text{HS}}^2 \right)^{1/2} \\ &= \frac{2}{(1-\epsilon)n} \left(\mathbf{E}_{X_i \sim \mathcal{P}_\# \phi} \mathbf{E}_{\xi_i \sim \mathcal{R}} \sum_{k=1}^p \left\langle \sum_{i=1}^{(1-\epsilon)n} \xi_i (X_i \otimes X_i) e_k, \sum_{j=1}^{(1-\epsilon)n} \xi_j (X_j \otimes X_j) e_k \right\rangle_{\mathcal{H}} \right)^{1/2} \\ &= \frac{2}{(1-\epsilon)n} \left(\mathbf{E}_{X_i \sim \mathcal{P}_\# \phi} \mathbf{E}_{\xi_i \sim \mathcal{R}} \sum_{k=1}^p \sum_{i=1}^{(1-\epsilon)n} \sum_{j=1}^{(1-\epsilon)n} \xi_i \xi_j \langle (X_i \otimes X_i) e_k, (X_j \otimes X_j) e_k \rangle_{\mathcal{H}} \right)^{1/2} \\ &\stackrel{(iv)}{=} \frac{2}{(1-\epsilon)n} \left(\mathbf{E}_{X_i \sim \mathcal{P}_\# \phi} \sum_{k=1}^p \sum_{i=1}^{(1-\epsilon)n} \langle (X_i \otimes X_i) e_k, (X_i \otimes X_i) e_k \rangle_{\mathcal{H}} \right)^{1/2} \\ &= \frac{2}{(1-\epsilon)n} \left(\sum_{i=1}^{(1-\epsilon)n} \mathbf{E}_{X_i \sim \mathcal{P}_\# \phi} \|X_i \otimes X_i\|_{\text{HS}}^2 \right)^{1/2} \\ &\stackrel{(v)}{=} \frac{2}{\sqrt{(1-\epsilon)n}} \left(\mathbf{E}_{X_i \sim \mathcal{P}_\# \phi} \|X_i\|_{\mathcal{H}}^4 \right)^{1/2} \end{aligned}$$

(iv) follows from noticing $\mathbf{E}_{\xi_i, \xi_j \sim \mathcal{R}} [\xi_i \xi_j] = \delta_{ij}$. (v) follows from expanding the Hilbert-Schmidt Norm and applying Parseval's Identity. We will now calculate the fourth moment of a norm of sub-Gaussian function in

the Hilbert Space.

$$\begin{aligned}
\mathbf{E}_{X \sim \mathcal{P}_\# \phi} [\|X\|_{\mathcal{H}}^4] &= \int_0^\infty \mathbf{Pr}_{X \sim \mathcal{P}_\# \phi} \left\{ \|X\|_{\mathcal{H}}^4 \geq t \right\} dt = \int_0^\infty \mathbf{Pr}_{X \sim \mathcal{P}_\# \phi} \left\{ \|X\|_{\mathcal{H}} \geq t^{1/4} \right\} dt \\
&\stackrel{(vi)}{\leq} \int_0^\infty \inf_{\theta > 0} \mathbf{E}_{X \sim \mathcal{P}_\# \phi} [\exp(\theta \|X\|_{\mathcal{H}})] \exp(-\theta t^{1/4}) dt \leq \int_0^\infty \inf_{\theta > 0} \exp\left(\frac{\theta^2 \|\Gamma\|_{\text{op}}}{2} - \theta t^{1/4}\right) dt \\
&= \int_0^\infty \exp\left(-\frac{\sqrt{t}}{\|\Gamma\|_{\text{op}}}\right) dt = 2 \|\Gamma\|_{\text{op}}^2
\end{aligned}$$

In (vi) we apply Markov's Inequality. From which we obtain,

$$\mathbf{E}_{X_i \sim \mathcal{P}_\# \phi} \left\| \frac{1}{(1-\epsilon)n} \sum_{i=1}^{(1-\epsilon)n} X_i \otimes X_i - \Sigma \right\|_{\text{HS}} \leq \sqrt{\frac{8}{(1-\epsilon)n}} \|\Gamma\|_{\text{op}}$$

Then, define the function $r(\mathbf{x}) : \mathcal{X} \rightarrow \mathcal{H} \otimes \mathcal{H}$, $\mathbf{x} \rightarrow \phi(\mathbf{x}) \otimes \phi(\mathbf{x})$. From Assumption 5, we have $r(\mathbf{x}) = \|\phi(\mathbf{x}) \otimes \phi(\mathbf{x})\|_{\text{HS}} \leq \|\phi(\mathbf{x})\|_{\mathcal{H}}^2 \leq P_k$. We will use McDiarmid's Inequality, consider $\tilde{P} \triangleq \delta_{X_i}$ with one modified element. Then consider the equation $f(x_1, \dots, x_n) : \mathcal{X} \times \dots \times \mathcal{X} \rightarrow \mathcal{H} \otimes \mathcal{H} \times \dots \times \mathcal{H} \otimes \mathcal{H}$, $x_1, \dots, x_n \rightarrow \left\| \int_{\mathcal{X}} r(x) dP_B(x) - \int_{\mathcal{X}} r(x) dP(x) \right\|_{\text{HS}}$.

$$\begin{aligned}
\left\| \int_{\mathcal{X}} r(x) dP_B(x) - \int_{\mathcal{X}} r(x) dP(x) \right\|_{\text{HS}} - \left\| \int_{\mathcal{X}} r(x) dP_{\tilde{B}}(x) - \int_{\mathcal{X}} r(x) dP(x) \right\|_{\text{HS}} \\
\leq \frac{1}{(1-\epsilon)n} (\|r(x_i)\|_{\text{HS}} + \|r(\tilde{x}_i)\|_{\text{HS}}) \leq \frac{2P_k}{(1-\epsilon)n}
\end{aligned}$$

Then, we have from McDiarmid's inequality (Proposition 18),

$$\mathbf{Pr} \left\{ \left\| \int_{\mathcal{X}} r(x) dP_B(x) - \int_{\mathcal{X}} r(x) dP(x) \right\|_{\text{HS}} - \sqrt{\frac{8}{(1-\epsilon)n}} \|\Gamma\|_{\text{op}} \geq t \right\} \leq \exp\left(-\frac{t^2(1-\epsilon)n}{P_k^2}\right)$$

We then have our first claim with probability exceeding $1 - \delta$,

$$\left\| \int_{\mathcal{X}} r(x) dP_B(x) - \int_{\mathcal{X}} r(x) dP(x) \right\|_{\text{HS}} \leq \sqrt{\frac{8}{(1-\epsilon)n}} \|\Gamma\|_{\text{op}} + \sqrt{\frac{P_k^2 \log(2/\delta)}{(1-\epsilon)n}}$$

Next, applying a union bound over \mathcal{S} with Fact 16, we have

$$\max_{B \in \mathcal{S}} \left\| \int_{\mathcal{X}} r(x) dP_B(x) - \int_{\mathcal{X}} r(x) dP(x) \right\|_{\text{HS}} \leq \sqrt{\frac{8}{(1-\epsilon)n}} \|\Gamma\|_{\text{op}} + \sqrt{\frac{P_k^2 \log(2/\delta)}{(1-\epsilon)n} + \frac{P_k^2 \epsilon \log \epsilon^{-1}}{(1-\epsilon)}}$$

Simplifying the resultant bound completes the proof. ■

B Proofs for Structural Results

In this section we give the deferred proofs of our main structural results of the subquantile objective function.

B.1 Collaboration as a Criterion for Independence

In this section we discuss collaboration in the corrupted covariates. We consider the problems of fastly finding collaborating covariates and the probability the good points are collaborative.

Lemma 21. *Consider a determinate set of numbers $(a_i)_{i=1}^n$, and determinate set of functions in the Hilbert Space, $(X_i)_{i=1}^n$. It then follows,*

$$\left\| \sum_{i=1}^n a_i X_i \right\|_{\mathcal{H}}^2 \leq \|\alpha\|_2^2 \|K\|$$

Proof. The proof is a calculation.

$$\begin{aligned} \left\| \sum_{i=1}^n \alpha_i X_i \right\|_{\mathcal{H}}^2 &\stackrel{(i)}{\leq} \|\alpha\|_2^2 \max_{\mathbf{v} \in \mathbb{S}^{n-1}} \left\| \sum_{i=1}^n v_i X_i \right\|_{\mathcal{H}}^2 = \|\alpha\|_2^2 \max_{\mathbf{v} \in \mathbb{S}^{n-1}} \left\langle \sum_{i=1}^n v_i X_i, \sum_{j=1}^n v_j X_j \right\rangle_{\mathcal{H}} \\ &= \|\alpha\|_2^2 \max_{\mathbf{v} \in \mathbb{S}^{n-1}} \sum_{i=1}^n \sum_{j=1}^n v_i v_j k(x_i, x_j) = \|\alpha\|_2^2 \max_{\mathbf{v} \in \mathbb{S}^{n-1}} \mathbf{v}^\top \mathbf{K} \mathbf{v} = \|\alpha\|_2^2 \|\mathbf{K}\| \end{aligned}$$

where $\mathbf{K} \triangleq [K]_{ij} = k(x_i, x_j)$. The inequality in (i) is the most important step, \mathbf{v} can be considered a unit weighting vector and we then multiply by the total weight. This inequality is sharp when $\alpha_i = \alpha_j$ for all $i, j \in [n]$. ■

Lemma 22. Let $(x_i)_{i=1}^n$ such that $X_i \triangleq \phi(x_i) \in \mathcal{H}$. Let $\mathbf{K} \in \mathbb{R}^{n \times n}$ s.t. $K_{ij} \triangleq k(x_i, x_j)$. Then it follows

$$\left\| \sum_{i=1}^n X_i \otimes X_i \right\|_{\mathcal{H} \rightarrow \mathcal{H}}^2 = \|\mathbf{K}\|^2$$

Proof.

$$\begin{aligned} \left\| \sum_{i=1}^n X_i \otimes X_i \right\|_{\mathcal{H} \rightarrow \mathcal{H}}^2 &= \max_{Y \in \mathcal{H}} \left\| \left[\sum_{i=1}^n X_i \otimes X_i \right] Y \right\|_{\mathcal{H}}^2 = \max_{Y \in \mathcal{H}} \left\| \sum_{i=1}^n X_i \langle X_i, Y \rangle_{\mathcal{H}} \right\|_{\mathcal{H}}^2 \\ &= \max_{Y \in \mathcal{H}} \sum_{i=1}^n \sum_{j=1}^n K_{ij} \langle X_i, Y \rangle_{\mathcal{H}} \langle X_j, Y \rangle_{\mathcal{H}} \end{aligned}$$

Let $\mathbf{v} \in \mathbb{R}^n$ s.t. $\mathbf{K} \mathbf{v} = \lambda_{\max}(\mathbf{K}) \mathbf{v}$. We thus have $\Phi(\mathbf{K} \mathbf{v}) = \lambda_{\max}(\mathbf{K}) \Phi \mathbf{v}$. Expanding out \mathbf{K} , we have $\Phi \otimes \Phi(\Phi \mathbf{v}) = \lambda_{\max}(\mathbf{K}) \Phi \mathbf{v}$. Alternatively, let $Y \in \mathcal{H}$ s.t. $[\Phi \otimes \Phi] Y = \lambda_{\max}(\Phi \otimes \Phi) Y$. Then, we have $\mathbf{K}(\Phi^* Y) = \lambda_{\max}(\Phi \otimes \Phi) \Phi^* Y$. Thus the maximum eigenvector of \mathbf{K} is equal to $\Phi^* Y$. ■

C Proofs for Kernelized Regression

We will first give a simple calculation of the β -smoothness parameter of the subquantile objective. We then will give proofs for our approximation error bounds.

C.1 Kernel Matrix Eigenvalue Concentration

Lemma 23. Let $X_1, \dots, X_n \sim \mathcal{P}_\# \phi$. Let \mathcal{S} represent all permutations of $[n]$ from size $[n(1-2\epsilon)]$ to $[(1-\epsilon)n]$. Form the kernel matrix $\mathbf{K} \in \mathbb{R}^{n \times n}$ s.t. $K_{ij} \triangleq k(\mathbf{x}_i, \mathbf{x}_j)$. Then with probability exceeding $1 - \delta$

$$\begin{aligned} \min_{A \in \mathcal{S}} \lambda_{\min}(\mathbf{K}_A) &\geq 0.5n(1-2\epsilon)\lambda_{\min}(\Gamma) \\ \max_{A \in \mathcal{S}} \lambda_{\max}(\mathbf{K}_A) &\leq 2(1-\epsilon)n\lambda_{\max}(\Gamma) \end{aligned}$$

$$n \geq (1-\epsilon)^{-1} \left(256 + 64 (P_k / \lambda_{\min}(\Gamma))^2 \log(2/\delta) \right) \text{ and } \epsilon \leq \frac{1}{32} (\lambda_{\min}(\Gamma) / P_k)^2.$$

Proof. We will give our probabilistic bounds using the first and second relation in our covariance estimation bound given in Proposition 20.

Lower Bound.

$$\begin{aligned} \|\mathbf{K}_A\| &= \|\mathbf{X}_A \otimes \mathbf{X}_A\|_{\text{op}} = \|n(1-2\epsilon)\Gamma + \mathbf{X}_A \otimes \mathbf{X}_A - n(1-2\epsilon)\Gamma\|_{\text{op}} \\ &\geq (1-\epsilon)n\lambda_{\min}(\Gamma) - \|\mathbf{X}_A \otimes \mathbf{X}_A - (1-\epsilon)n\Gamma\|_{\text{op}} \\ &\geq (1-\epsilon)n \left(\lambda_{\min}(\Gamma) - P_k \sqrt{\frac{\epsilon \log \epsilon^{-1}}{(1-\epsilon)}} \right) - \sqrt{(1-\epsilon)n} \left(\sqrt{8} \lambda_{\min}(\Gamma) + \sqrt{2P_k^2 \log(2/\delta)} \right) \end{aligned}$$

$$\geq (1/2)(1 - \epsilon)n\lambda_{\min}(\Gamma)$$

when $n \geq (1 - \epsilon)^{-1} \left(256 + 64 (P_k / \lambda_{\min}(\Gamma))^2 \log(2/\delta) \right)$ and $\epsilon \leq \frac{1}{32} \left(\frac{\lambda_{\min}(\Gamma)}{P_k} \right)^2$ with probability exceeding $1 - \delta$.

Upper Bound.

$$\begin{aligned} \|K_A\| &\leq \|K_P\| = \|X_P \otimes X_P\|_{\text{op}} \\ &\leq (1 - \epsilon)n\lambda_{\max}(\Gamma) + \sqrt{(1 - \epsilon)n} \left(\sqrt{8}\lambda_{\max}(\Gamma) + \sqrt{2P_k^2 \log(2/\delta)} \right) \\ &\leq 2(1 - \epsilon)n\lambda_{\max}(\Gamma) \end{aligned}$$

when $n \geq (1 - \epsilon)^{-1} \left(16 + 4 \left(P_k / \|\Gamma\|_{\text{op}} \right)^2 \log(2/\delta) \right)$. This completes the proof. \blacksquare

C.2 Matrix Eigenvalue Concentration

First we will give our bounded covariate corruption assumption.

Assumption 24 (Bounded Covariate Corruption). *There exists a constants C_1, C_2 , such that*

$$\|\Pi X_{\text{FP}}\|_2 \leq \sqrt{\epsilon n C_1} \quad \text{and} \quad \|(I - \Pi)X_{\text{FP}}\|_2 \leq \sqrt{\epsilon n C_2}$$

Lemma 25 (Norm of Subset of Good Covariates). *Let X_* represent a subset of the good data, then it follows,*

$$\|X_*\|_2 \leq \sqrt{n \|\Gamma\|}$$

C.3 Proof of Theorem 9

First we give the necessary results for our analysis.

Lemma 26 (Lemma 3.11 [B⁺15]). *Let f be β -smooth and α -strongly convex over \mathbb{R}^n , then for all $\mathbf{x}, \mathbf{y} \in \mathbb{R}^n$, it follows,*

$$\langle \nabla f(\mathbf{x}) - \nabla f(\mathbf{y}), \mathbf{x} - \mathbf{y} \rangle \geq \frac{\alpha\beta}{\alpha + \beta} \|\mathbf{x} - \mathbf{y}\|^2 + \frac{1}{\alpha + \beta} \|\nabla f(\mathbf{x}) - \nabla f(\mathbf{y})\|^2$$

Proposition 27 (Young's Inequality [You12]). *Suppose $a, b \in \mathbb{R}_+$, then for $p, q > 1$ such that $\frac{1}{p} + \frac{1}{q} = 1$, it follows*

$$ab \leq \frac{a^p}{p} + \frac{b^q}{q}$$

We are now ready to prove our main approximation bound.

Proof. Recall, we have

$$\mathbf{w}^{(t+1)} = \mathbf{w}^{(t)} - \frac{2\eta}{(1 - \epsilon)n} \sum_{i \in S^{(t)}} (\mathbf{x}_i^T \mathbf{w}^{(t)} - y_i)$$

We then have by the definition of the projector,

$$\|\mathbf{w}^{(t)} - \mathbf{w}^*\|_2^2 = \|\Pi[\mathbf{w}^{(t)} - \mathbf{w}^*]\|_2^2 + \|(I - \Pi)[\mathbf{w}^{(t)} - \mathbf{w}^*]\|_2^2$$

We will first focusing on the approximation over the projection onto Ψ . Recall the partitions $S^{(t)} = (S^{(t)} \cap P) \cup (S^{(t)} \cap Q) \triangleq \text{TP} \cup \text{FP}$ as the *True Positives* and *False Positives*. Similarly, $X \setminus S^{(t)} = ((X \setminus S^{(t)}) \cap P) \cup ((X \setminus S^{(t)}) \cap Q) \triangleq \text{FN} \cup \text{TN}$ represent the *False Negatives* and *True Negatives*.

$$\begin{aligned} \|\Pi[\mathbf{w}^{(t)} - \mathbf{w}^*]\|_2 &= \|\Pi[\mathbf{w}^{(t)} - \mathbf{w}^* - \nabla_{\mathbf{w}} \mathcal{R}_{S^{(t)}}(\mathbf{w}^{(t)})]\|_2 \\ &= \|\Pi[\mathbf{w}^{(t)} - \mathbf{w}^* - \eta \nabla_{\mathbf{w}} \mathcal{R}_{\text{TP}}(\mathbf{w}) + \eta \nabla_{\mathbf{w}} \mathcal{R}_{\text{TP}}(\mathbf{w}^*) + \eta \nabla_{\mathbf{w}} \mathcal{R}_{\text{FP}}(\mathbf{w}^{(t)}) + \eta \nabla_{\mathbf{w}} \mathcal{R}_{\text{FN}}(\mathbf{w}^*)]\| \end{aligned}$$

$$\leq \|\Pi[\mathbf{w}^{(t)} - \mathbf{w}^* - \eta \nabla_{\mathbf{w}} \mathcal{R}_{\text{TP}}(\mathbf{w}) + \eta \nabla_{\mathbf{w}} \mathcal{R}_{\text{TP}}(\mathbf{w}^*)]\|_2 + \|\eta \Pi[\nabla_{\mathbf{w}} \mathcal{R}_{\text{FP}}(\mathbf{w}^{(t)})]\|_2 + \|\eta \Pi[\nabla_{\mathbf{w}} \mathcal{R}_{\text{FN}}(\mathbf{w}^*)]\|_2$$

In the above, in the first inequality we note that $\nabla_{\mathbf{w}} \mathcal{R}(\mathbf{w}^*) = \nabla_{\mathbf{w}} \mathcal{R}_{\text{TP}}(\mathbf{w}^*) + \nabla_{\mathbf{w}} \mathcal{R}_{\text{FN}}(\mathbf{w}^*) = \mathbf{0}$, and in the second inequality the triangle inequality is applied twice. We first bound the first term through the square, we obtain,

$$\begin{aligned} & \|\Pi[\mathbf{w}^{(t)} - \mathbf{w}^* - \eta \nabla_{\mathbf{w}} \mathcal{R}_{\text{TP}}(\mathbf{w}) + \eta \nabla_{\mathbf{w}} \mathcal{R}_{\text{TP}}(\mathbf{w}^*)]\|_2^2 \\ &= \|\Pi[\mathbf{w}^{(t)} - \mathbf{w}^*]\|_2^2 - 2 \left\langle \Pi[\mathbf{w}^{(t)} - \mathbf{w}^*], \Pi[\nabla_{\mathbf{w}} \mathcal{R}_{\text{TP}}(\mathbf{w}) - \nabla_{\mathbf{w}} \mathcal{R}_{\text{TP}}(\mathbf{w}^*)] \right\rangle \\ & \quad + \|\Pi[\eta \nabla_{\mathbf{w}} \mathcal{R}_{\text{TP}}(\mathbf{w}^{(t)}) - \eta \nabla_{\mathbf{w}} \mathcal{R}_{\text{TP}}(\mathbf{w}^*)]\|_2^2 \end{aligned} \quad (2)$$

Expanding the gradient over the *True Positives*, we have

$$\begin{aligned} & \Pi[\nabla_{\mathbf{w}} \mathcal{R}_{\text{TP}}(\mathbf{w}) - \nabla_{\mathbf{w}} \mathcal{R}_{\text{TP}}(\mathbf{w}^*)] \\ &= \Pi \left[\frac{2}{(1-\epsilon)n} \sum_{i \in \text{TP}} (\mathbf{x}_i^T \mathbf{w}^{(t)} - \mathbf{x}_i^T \mathbf{w}^*) \cdot \mathbf{x}_i \right] = \frac{2}{(1-\epsilon)n} \sum_{i \in \text{TP}} \Pi[\mathbf{x}_i] \mathbf{x}_i^T (\mathbf{w}^{(t)} - \mathbf{w}^*) \\ &= \frac{2}{(1-\epsilon)n} \sum_{i \in \text{TP}} \Pi[\mathbf{x}_i] \left(\Pi[\mathbf{x}_i]^T (\Pi[\mathbf{w}^{(t)} - \mathbf{w}^*]) + (\mathbf{I} - \Pi)[\mathbf{x}_i]^T ((\mathbf{I} - \Pi)[\mathbf{w}^{(t)} - \mathbf{w}^*]) \right) \\ &= \nabla_{\mathbf{w}} \Pi \mathcal{R}_{\text{TP}}(\Pi \mathbf{w}^{(t)}) - \nabla_{\mathbf{w}} \Pi \mathcal{R}_{\text{TP}}(\Pi \mathbf{w}^*) + \Pi[\nabla_{\mathbf{w}} \mathcal{R}_{\text{TP}}((\mathbf{I} - \Pi)\mathbf{w}) - \nabla_{\mathbf{w}} \mathcal{R}_{\text{TP}}((\mathbf{I} - \Pi)\mathbf{w}^*)] \end{aligned} \quad (3)$$

where in the final inequality, we define the function, $\Pi \mathcal{R}_{\text{TP}}(\mathbf{w}) \triangleq \sum_{i \in \text{TP}} (\Pi[\mathbf{x}_i]^T \mathbf{w} - y_i)^2$. Then for the third term in Equation 2, we have

$$\begin{aligned} \|\eta \Pi[\nabla_{\mathbf{w}} \mathcal{R}_{\text{TP}}(\mathbf{w}^{(t)}) - \nabla_{\mathbf{w}} \mathcal{R}_{\text{TP}}(\mathbf{w}^*)]\|_2^2 &\leq 2\eta^2 \cdot \|\nabla_{\mathbf{w}} \Pi \mathcal{R}_{\text{TP}}(\Pi \mathbf{w}^{(t)}) - \nabla_{\mathbf{w}} \Pi \mathcal{R}_{\text{TP}}(\Pi \mathbf{w}^*)\|_2^2 \\ &\quad + 2\eta^2 \cdot \|\nabla_{\mathbf{w}} \Pi[\mathcal{R}_{\text{TP}}((\mathbf{I} - \Pi)\mathbf{w}^{(t)})] - \nabla_{\mathbf{w}} \Pi[\mathcal{R}_{\text{TP}}((\mathbf{I} - \Pi)\mathbf{w}^*)]\|_2^2 \end{aligned}$$

where we apply the triangle inequality and the elementary inequality $(a + b)^2 \leq 2a^2 + 2b^2$. For clarity, we also have from Equation 3 the following equality,

$$\begin{aligned} 2\eta \left\langle \Pi[\mathbf{w}^{(t)} - \mathbf{w}^*], \Pi[\nabla_{\mathbf{w}} \mathcal{R}_{\text{TP}}(\mathbf{w}) - \nabla_{\mathbf{w}} \mathcal{R}_{\text{TP}}(\mathbf{w}^*)] \right\rangle &= 2\eta \left\langle \Pi[\mathbf{w}^{(t)} - \mathbf{w}^*], \nabla_{\mathbf{w}} \Pi \mathcal{R}_{\text{TP}}(\Pi \mathbf{w}^{(t)}) - \nabla_{\mathbf{w}} \Pi \mathcal{R}_{\text{TP}}(\Pi \mathbf{w}^*) \right\rangle \\ &\quad + 2\eta \left\langle \Pi[\mathbf{w}^{(t)} - \mathbf{w}^*], \Pi[\nabla_{\mathbf{w}} \mathcal{R}_{\text{TP}}((\mathbf{I} - \Pi)\mathbf{w}) - \nabla_{\mathbf{w}} \mathcal{R}_{\text{TP}}((\mathbf{I} - \Pi)\mathbf{w}^*)] \right\rangle \end{aligned} \quad (4)$$

We can now note the following relation,

$$\sum_{i \in \text{TP}} \Pi \mathbf{x}_i \mathbf{x}_i^T = \sum_{i \in \text{TP}} \Pi \mathbf{x}_i \mathbf{x}_i^T \Pi + \sum_{i \in \text{TP}} \Pi \mathbf{x}_i \mathbf{x}_i^T (\mathbf{I} - \Pi) = \Pi \mathbf{X}_{\text{TP}} \mathbf{X}_{\text{TP}}^T \Pi + \Pi \mathbf{X}_{\text{TP}} \mathbf{X}_{\text{TP}}^T (\mathbf{I} - \Pi) \quad (5)$$

Then we can bound the second term in Equation 4.

$$\begin{aligned} & 2\eta \cdot \left\langle \Pi[\mathbf{w}^{(t)} - \mathbf{w}^*], \Pi[\nabla_{\mathbf{w}} \mathcal{R}_{\text{TP}}((\mathbf{I} - \Pi)\mathbf{w}) - \nabla_{\mathbf{w}} \mathcal{R}_{\text{TP}}((\mathbf{I} - \Pi)\mathbf{w}^*)] \right\rangle \\ & \stackrel{(5)}{=} \frac{4\eta}{(1-\epsilon)n} \cdot \Pi[\mathbf{w}^{(t)} - \mathbf{w}^*]^T \Pi \mathbf{X}_{\text{TP}}^T (\mathbf{I} - \Pi) [\mathbf{X}_{\text{TP}}] (\mathbf{I} - \Pi) [\mathbf{w}^{(t)} - \mathbf{w}^*] \\ & \leq \frac{\eta}{2(1-\epsilon)n} \|\Pi[\mathbf{w}^{(t)} - \mathbf{w}^*]\|_2^2 \|(\mathbf{I} - \Pi) [\mathbf{X}_{\text{TP}}]\|_2^2 + \frac{8\eta}{(1-\epsilon)n} \|(\mathbf{I} - \Pi) [\mathbf{w}^{(t)} - \mathbf{w}^*]\|_2^2 \|\Pi \mathbf{X}_{\text{TP}}^T\|_2^2 \end{aligned} \quad (6)$$

In the above, in the first inequality we use Young's inequality with $p = q = 2$ (see Proposition 27). We then have for $\Pi \mathcal{R}_{\text{TP}}$ the strong convexity and smoothness coefficients, $\alpha = \frac{1}{(1-\epsilon)n} \lambda_{\min} (\Pi \mathbf{X}_{\text{TP}}^T \mathbf{X}_{\text{TP}}^T \Pi)$ and $\beta = \frac{2}{(1-\epsilon)n} \lambda_{\max} (\Pi \mathbf{X}_{\text{TP}}^T \mathbf{X}_{\text{TP}}^T \Pi) = \frac{2}{(1-\epsilon)n} \|\Pi \mathbf{X}_{\text{TP}}\|_2^2$. Then, from Lemma 26, we have

$$\begin{aligned} & \left\langle \Pi[\mathbf{w}^{(t)} - \mathbf{w}^*], \eta \nabla_{\mathbf{w}} \Pi \mathcal{R}_{\text{TP}}(\Pi \mathbf{w}^{(t)}) - \eta \nabla_{\mathbf{w}} \Pi \mathcal{R}_{\text{TP}}(\Pi \mathbf{w}^*) \right\rangle \\ & \geq \frac{\eta}{2(1-\epsilon)n} \lambda_{\min}(\Pi X_{\text{TP}} X_{\text{TP}}^T \Pi) \|\Pi[\mathbf{w}^{(t)} - \mathbf{w}^*]\|_2^2 + \frac{\eta}{2 \|\Pi X_{\text{TP}}\|^2} \|\nabla_{\mathbf{w}} \Pi \mathcal{R}(\mathbf{w}^{(t)}) - \nabla_{\mathbf{w}} \Pi \mathcal{R}(\mathbf{w}^*)\|^2 \end{aligned} \quad (7)$$

Noting that $\lambda_{\min}(\Pi X_{\text{TP}} X_{\text{TP}}^T \Pi) \geq \lambda_{\max}((I - \Pi) X_{\text{TP}} X_{\text{TP}}^T (I - \Pi))$, when $\eta \leq (1/2\beta)$, we obtain

$$\begin{aligned} \|\Pi[\mathbf{w}^{(t)} - \mathbf{w}^* - \eta \nabla_{\mathbf{w}} \mathcal{R}_{\text{TP}}(\mathbf{w}) + \eta \nabla_{\mathbf{w}} \mathcal{R}_{\text{TP}}(\mathbf{w}^*)]\|_2 & \leq \|\Pi[\mathbf{w}^{(t)} - \mathbf{w}^*]\|_2 \sqrt{1 - \frac{\eta}{2(1-\epsilon)n} \cdot \lambda_{\min}(\Pi X_{\text{TP}} X_{\text{TP}}^T \Pi)} \\ & \quad + \|(I - \Pi)[\mathbf{w}^{(t)} - \mathbf{w}^*]\|_2 \sqrt{\frac{8\eta}{(1-\epsilon)n} \|\Pi X_{\text{TP}}^T\|_2^2 + \frac{2\eta^2}{[(1-\epsilon)n]^2} \|\Pi X_{\text{TP}}\|^2 \|(I - \Pi) X_{\text{TP}}\|^2} \end{aligned} \quad (8)$$

For the first term we combine Equations 6 and 7, for second term we use Equation 6. Then we can note for $x \leq 1$, we have $\sqrt{1-x} \leq 1 - (x/2)$. We continue our analysis.

$$\|\Pi[\nabla_{\mathbf{w}} \mathcal{R}_{\text{FN}}(\mathbf{w}^*)]\|_2^2 = \left\| \frac{1}{(1-\epsilon)n} \sum_{i \in \text{TP}} \xi_i \Pi \mathbf{x}_i \right\|_2^2 = \frac{\boldsymbol{\xi}_{\text{FN}}^T \Pi X_{\text{FN}} X_{\text{FN}}^T \Pi \boldsymbol{\xi}_{\text{FN}}}{[(1-\epsilon)n]^2} = O\left(\frac{\sigma \|\Pi X_{\text{FN}} X_{\text{FN}}^T \Pi\|_*}{[(1-\epsilon)n]^2}\right) \quad (9)$$

This is equivalent to Trace Estimation with a normal vector. We now upper bound the corrupted part of the gradient.

$$\begin{aligned} \|\Pi[\nabla_{\mathbf{w}} \mathcal{R}_{\text{FP}}(\mathbf{w}^{(t)})]\|_2^2 & = \left\| \frac{1}{(1-\epsilon)n} \sum_{i \in \text{FP}} (\mathbf{x}_i^T \mathbf{w}^{(t)} - y_i) \cdot \Pi \mathbf{x}_i \right\|_2^2 \\ & \leq \frac{1}{[(1-\epsilon)n]^2} \cdot \|\Pi X_{\text{FP}}\|_2^2 \|\mathbf{X}_{\text{FP}}^T \mathbf{w}^{(t)} - \mathbf{y}_{\text{FP}}\|_2^2 \leq \frac{1}{[(1-\epsilon)n]^2} \cdot \|\Pi X_{\text{FP}}\|_2^2 \|\mathbf{X}_{\text{FN}}^T \mathbf{w}^{(t)} - \mathbf{y}_{\text{FN}}\|_2^2 \\ & \leq \frac{2}{[(1-\epsilon)n]^2} \cdot \|\Pi X_{\text{FP}}\|_2^2 \left(\|\mathbf{X}_{\text{FN}}^T (\mathbf{w}^{(t)} - \mathbf{w}^*)\|_2^2 + \|\boldsymbol{\xi}_{\text{FN}}\|^2 \right) \\ & \leq \frac{4}{[(1-\epsilon)n]^2} \cdot \|\Pi X_{\text{FP}}\|_2^2 \left(\|\Pi[\mathbf{X}_{\text{FN}}^T]\|_2^2 \|\Pi[\mathbf{w}^{(t)} - \mathbf{w}^*]\|_2^2 + \|(I - \Pi)[\mathbf{X}_{\text{FN}}^T]\|_2^2 \|(I - \Pi)[\mathbf{w}^{(t)} - \mathbf{w}^*]\|_2^2 \right) \\ & \quad + \frac{2}{[(1-\epsilon)n]^2} \cdot \|\Pi X_{\text{FP}} X_{\text{FP}}^T \Pi\|_2 \|\boldsymbol{\xi}_{\text{FN}}\|^2 \end{aligned} \quad (10)$$

In the above, in the second inequality we used the optimality of the subquantile set. In the third and fourth inequalities we used the simple inequality $(a+b)^2 \leq 2a^2 + 2b^2$. Then, we have

$$\begin{aligned} \|\Pi[\mathbf{w}^{(t+1)} - \mathbf{w}^*]\|_2 & \leq \|\Pi[\mathbf{w}^{(t)} - \mathbf{w}^*]\|_2 \left(1 - \frac{\eta}{4(1-\epsilon)n} \lambda_{\min}(\Pi X_{\text{TP}} X_{\text{TP}}^T \Pi) + \frac{2\eta}{(1-\epsilon)n} \|\Pi[\mathbf{X}_{\text{FP}}]\|_2 \|\Pi[\mathbf{X}_{\text{FN}}]\|_2 \right) \\ & \quad + \|(I - \Pi)[\mathbf{w}^{(t)} - \mathbf{w}^*]\|_2 \left(\frac{2\eta}{(1-\epsilon)n} \|\Pi[\mathbf{X}_{\text{FP}}]\|_2 \|(I - \Pi)[\mathbf{X}_{\text{FN}}]\|_2 + \sqrt{\frac{8\eta}{(1-\epsilon)n} \|\Pi X_{\text{TP}}^T\|_2} \right. \\ & \quad \left. + \frac{\sqrt{2}\eta}{(1-\epsilon)n} \|\Pi X_{\text{TP}}^T\|_2 \|(I - \Pi)[\mathbf{X}_{\text{TP}}]\|_2 \right) + O\left(\frac{\sigma \|\Pi X_{\text{FN}} X_{\text{FN}}^T \Pi\|_*}{[(1-\epsilon)n]^2}\right) + \frac{2\eta^2}{[(1-\epsilon)n]^2} \cdot \|\Pi X_{\text{FP}} X_{\text{FP}}^T \Pi\|_2 \|\boldsymbol{\xi}_{\text{FN}}\|^2 \end{aligned}$$

where we combine Equations 8, 9, and 10. From the assumption that $\mathbf{w}^{(0)} = \mathbf{0}$, we have that $\|(I - \Pi)[\mathbf{w}^{(0)} - \mathbf{w}^*]\| = \|(I - \Pi)\mathbf{w}^*\|$. Furthermore, we have the following simple calculation,

$$\begin{aligned} \|(I - \Pi)[\mathbf{w}^{(t+1)} - \mathbf{w}^*]\|_2 & = \|(I - \Pi)[\mathbf{w}^{(t)} - \mathbf{w}^* - \nabla_{\mathbf{w}} \mathcal{R}_{\text{S}^{(t)}}(\mathbf{w}^{(t)})]\|_2 \\ & \leq \|(I - \Pi)[\mathbf{w}^{(t)} - \mathbf{w}^*]\|_2 + \left\| \frac{\eta}{n(1-\epsilon)} \sum_{i \in \text{S}^{(t)}} (\mathbf{x}_i^T \mathbf{w}^{(t)} - y_i) \cdot (I - \Pi)\mathbf{x}_i \right\|_2 \\ & \leq \|(I - \Pi)[\mathbf{w}^{(t)} - \mathbf{w}^*]\|_2 + \frac{\eta}{(1-\epsilon)n} \|\mathbf{y}_{\text{S}^{(t)}}\|_2 \|(I - \Pi) X_{\text{S}^{(t)}}\|_2 \end{aligned}$$

Then, from the recursion obtained we have for any t ,

$$\|(\mathbf{I} - \Pi)[\mathbf{w}^{(t+1)} - \mathbf{w}^*]\|_2 \leq \|(\mathbf{I} - \Pi)\mathbf{w}^*\|_2 + \frac{t\eta}{(1-\epsilon)n} \|\mathbf{y}_{S^{(t)}}\|_2 \|(\mathbf{I} - \Pi)\mathbf{X}_{S^{(t)}}\|_2$$

■

D Proofs for Kernelized GLMs

In this section, we will prove error bounds for Subquantile Minimization in the Kernelized Binary Classification Problem.

D.1 Proof of Theorem 14 (In Progress)

Proof. From Algorithm 1, we have for the generalized linear model.

$$f^{(t+1)} = f^{(t)} - \frac{\eta}{(1-\epsilon)n} \cdot \sum_{i \in S^{(t)}} (\omega(f^{(t)}(\mathbf{x}_i)) - y_i) \cdot \omega'(f^{(t)}(\mathbf{x}_i)) \cdot X_i$$

We then have,

$$\begin{aligned} \|f^{(t+1)} - f^*\|_{\mathcal{H}} &= \|f^{(t)} - \eta \nabla_f \mathcal{R}_{S^{(t)}}(f^{(t)}) - f^*\|_{\mathcal{H}} \\ &= \|f^{(t)} - f^* - \eta \nabla \mathcal{R}_{\text{TP}}(f^{(t)}) - \eta \nabla \mathcal{R}_{\text{FP}}(f^{(t)})\|_{\mathcal{H}} \\ &\leq \|f^{(t)} - f^* - \eta \nabla \mathcal{R}_{\text{TP}}(f^{(t)})\|_{\mathcal{H}} + \|\eta \nabla \mathcal{R}_{\text{FP}}(f^{(t)})\|_{\mathcal{H}} \end{aligned} \quad (11)$$

We will now analyze the first term of Equation 11 through its square,

$$\|f^{(t)} - f^* - \eta \nabla \mathcal{R}_{\text{TP}}(f^{(t)})\|_{\mathcal{H}}^2 = \|f^{(t)} - f^*\|_{\mathcal{H}}^2 - 2\eta \cdot \left\langle f^{(t)} - f^*, \nabla \mathcal{R}_{\text{TP}}(f^{(t)}) \right\rangle_{\mathcal{H}} + \eta^2 \cdot \|\nabla \mathcal{R}_{\text{TP}}(f^{(t)})\|_{\mathcal{H}}^2 \quad (12)$$

We then have,

$$\begin{aligned} \left\langle f^{(t)} - f^*, \nabla \mathcal{R}_{\text{TP}}(f^{(t)}) \right\rangle_{\mathcal{H}} &\stackrel{\text{def}}{=} \left\langle f^{(t)} - f^*, \sum_{i \in \text{TP}} ((\omega(f^{(t)}(\mathbf{x}_i)) - \omega(f^*(\mathbf{x}_i)) - \xi_i) \cdot \omega'(f^{(t)}(\mathbf{x}_i)) \cdot X_i) \right\rangle_{\mathcal{H}} \\ &\geq C_1 \left\langle f^{(t)} - f^*, \sum_{i \in \text{TP}} ((\omega(f^{(t)}(\mathbf{x}_i)) - \omega(f^*(\mathbf{x}_i))) \cdot X_i) \right\rangle_{\mathcal{H}} - \left\langle f^{(t)} - f^*, \sum_{i \in \text{TP}} \xi_i X_i \right\rangle_{\mathcal{H}} \end{aligned}$$

Then, consider the function, $h : \mathcal{H} \rightarrow \mathbb{R}$, for a Dirac measure $P(X) = \frac{1}{|\text{TP}|} \delta_{\text{TP}}(X)$.

$$h(f) \triangleq \int_{\mathcal{H}} \left(\int \omega(y) dy \right) (f(X)) dP(X)$$

The first derivative gives us the following,

$$\nabla h(f) \triangleq \int_{\mathcal{H}} \omega(f(X)) \cdot X dP(X)$$

From which we have the following,

$$\nabla^2 h(f) \triangleq \int_{\mathcal{H}} \omega'(f(X)) \cdot X \otimes X dP(X) \succcurlyeq \min_{y \in \mathbb{R}} \omega'(y) \cdot \lambda_{\min} \left(\int_{\mathcal{H}} X \otimes X dP(X) \right) \stackrel{\text{def}}{=} C_1 \lambda_{\min} \left(\int_{\mathcal{H}} X \otimes X dP(X) \right)$$

Then from the strong convexity of $\int \omega(y) dy$ we have,

$$2\eta \left\langle f^{(t)} - f^*, \nabla \mathcal{R}_{\text{TP}}(f^{(t)}) \right\rangle_{\mathcal{H}} \geq \frac{2\eta C_1 \lambda_{\min}(X_{\text{TP}} \otimes X_{\text{TP}})}{(1-\epsilon)n} \|f^{(t)} - f^*\|_{\mathcal{H}}^2$$

Then for the third term of Equation 12, we have

$$\begin{aligned}
\|\eta \nabla \mathcal{R}_{\text{TP}}(f^{(t)})\|_{\mathcal{H}}^2 &\stackrel{\text{def}}{=} \frac{\eta^2}{[(1-\epsilon)n]^2} \cdot \left\| \sum_{i \in \text{TP}} (\omega(f^{(t)}(\mathbf{x}_i)) - y_i) \cdot \omega'(f^{(t)}(\mathbf{x}_i)) \cdot X_i \right\|_{\mathcal{H}}^2 \\
&= \frac{\eta^2}{[(1-\epsilon)n]^2} \cdot \left\| \sum_{i \in \text{TP}} (\omega(f^{(t)}(\mathbf{x}_i)) - \omega(f^*(\mathbf{x}_i)) + \xi_i) \cdot \omega'(f^{(t)}(\mathbf{x}_i)) \cdot X_i \right\|_{\mathcal{H}}^2 \\
&\leq \frac{\eta^2}{[(1-\epsilon)n]^2} \cdot \left\| \sum_{i \in \text{TP}} X_i \otimes X_i \right\|_{\text{op}} \sum_{i \in \text{TP}} (\omega(f^{(t)}(\mathbf{x}_i)) - \omega(f^*(\mathbf{x}_i)) + \xi_i)^2 \cdot \omega'(f^{(t)}(\mathbf{x}_i))^2 \\
&\leq \frac{2C_2^4 \eta^2}{[(1-\epsilon)n]^2} \cdot \left\| \sum_{i \in \text{TP}} X_i \otimes X_i \right\|_{\text{op}} \sum_{i \in \text{TP}} ((f^{(t)}(\mathbf{x}_i) - f^*(\mathbf{x}_i))^2 + \xi_i^2)
\end{aligned}$$

In the above, in the second inequality we utilize the elementary inequality $(a+b)^2 \leq 2a^2 + 2b^2$. Combining, the following holds,

$$\|f^{(t)} - f^* - \eta \nabla \mathcal{R}_{\text{TP}}(f^{(t)})\|_{\mathcal{H}}^2 \leq \|f^{(t)} - f^*\|_{\mathcal{H}}^2 \left(1 - \frac{\eta C_1 \lambda_{\min}(\mathbf{X}_{\text{TP}} \otimes \mathbf{X}_{\text{TP}})}{(1-\epsilon)n} \right) \quad (13)$$

We now will look at the second term of Equation 11.

$$\begin{aligned}
\|\eta \nabla \mathcal{R}_{\text{FP}}(f^{(t)})\|_{\mathcal{H}}^2 &\stackrel{\text{def}}{=} \frac{\eta^2}{[(1-\epsilon)n]^2} \cdot \left\| \sum_{i \in \text{FP}} (\omega(f^{(t)}(\mathbf{x}_i)) - y_i) \cdot \omega'(f^{(t)}(\mathbf{x}_i)) \cdot X_i \right\|_{\mathcal{H}}^2 \\
&\leq \frac{\eta^2}{[(1-\epsilon)n]^2} \cdot \left\| \sum_{i \in \text{FP}} X_i \otimes X_i \right\|_{\text{op}} \sum_{i \in \text{FP}} (\omega(f^{(t)}(\mathbf{x}_i)) - y_i)^2 \cdot \omega'(f^{(t)}(\mathbf{x}_i))^2 \\
&\leq \frac{C_2 \eta^2}{[(1-\epsilon)n]^2} \cdot \left\| \sum_{i \in \text{FP}} X_i \otimes X_i \right\|_{\text{op}} \sum_{i \in \text{FN}} (\omega(f^{(t)}(\mathbf{x}_i)) - y_i)^2 \\
&= \frac{C_2 \eta^2}{[(1-\epsilon)n]^2} \cdot \left\| \sum_{i \in \text{FP}} X_i \otimes X_i \right\|_{\text{op}} \sum_{i \in \text{FN}} (\omega(f^{(t)}(\mathbf{x}_i)) - \omega(f^*(\mathbf{x}_i) + \xi_i))^2 \\
&\leq \frac{C_2^2 \eta^2}{[(1-\epsilon)n]^2} \cdot \left\| \sum_{i \in \text{FP}} X_i \otimes X_i \right\|_{\text{op}} \left(\sum_{i \in \text{FN}} (f^{(t)}(\mathbf{x}_i) - f^*(\mathbf{x}_i))^2 + \xi_i^2 \right) \\
&\leq \frac{2C_2^2 \eta^2}{[(1-\epsilon)n]^2} \cdot \left\| \sum_{i \in \text{FP}} X_i \otimes X_i \right\|_{\text{op}} \left(\left\| \sum_{i \in \text{FN}} X_i \otimes X_i \right\|_{\text{op}} \|f^{(t)} - f^*\|_{\mathcal{H}}^2 + \|\boldsymbol{\xi}_{\text{FN}}\|^2 \right) \quad (14)
\end{aligned}$$

In the above, the first inequality follows from Lemma 21, the second inequality follows from the optimality of the Subquantile set and the bounded link function gradient. The third inequality follows from noting for any $x, y \in \mathbb{R}$, the bounded gradient implies Lipschitzness, i.e. $|\omega(x) - \omega(y)| \leq C_2|x - y|$. The final equality follows from the following,

$$\begin{aligned}
\sum_{i \in \text{FN}} (f^{(t)}(\mathbf{x}_i) - f^*(\mathbf{x}_i))^2 &= \left\langle f^{(t)} - f^*, \left[\sum_{i \in \text{FN}} X_i \otimes X_i \right] (f^{(t)} - f^*) \right\rangle_{\mathcal{H}} \stackrel{\text{def}}{=} \|f^{(t)} - f^*\|_{\Sigma_{\text{FN}}, \mathcal{H}}^2 \\
&\leq \|f^{(t)} - f^*\|_{\mathcal{H}}^2 \left\| \sum_{i \in \text{FN}} X_i \otimes X_i \right\|_{\text{op}}
\end{aligned}$$

Then from combining Equations 13 and 14 we have

$$\begin{aligned}
\|f^{(t+1)} - f^*\|_{\mathcal{H}} &\leq \|f^{(t)} - f^*\|_{\mathcal{H}} \left(1 - \eta \left(\frac{\lambda_{\min}(\mathbf{X}_{\text{TP}} \otimes \mathbf{X}_{\text{TP}})}{2(1-\epsilon)n} - \frac{C_2 \sqrt{2 \left\| \sum_{i \in \text{FP}} X_i \otimes X_i \right\|_{\text{op}} \left\| \sum_{i \in \text{FN}} X_i \otimes X_i \right\|_{\text{op}}}}{(1-\epsilon)n} \right) \right) \\
&\quad + \frac{\eta C_2 \|\boldsymbol{\xi}_{\text{FN}}\| \left(\sqrt{\left\| \sum_{i \in \text{FN}} X_i \otimes X_i \right\|_{\text{op}}} + \sqrt{\left\| \sum_{i \in \text{FP}} X_i \otimes X_i \right\|_{\text{op}}} \right)}{(1-\epsilon)n}
\end{aligned}$$

■

Table 1: Notations for Kernelized Regression

Symbol	Definition	Takes Values In
$g(f, t)$	Subquantile Function	$\mathcal{H} \times \mathbb{R} \rightarrow \mathbb{R}$
\mathcal{P}	Distribution of Good Data in the input space \mathcal{X}	$(\mathcal{X}, \mathcal{A}, \mathbf{Pr})$
$\phi(\mathbf{x}_i)$	Feature Transform Function	$\mathcal{X} \rightarrow \mathcal{H}$
ξ_i	Gaussian Noise, $\xi_i \sim \mathcal{N}(0, \sigma^2)$	\mathbb{R}
Φ_A	Quasimatrix (columns represent Hilbert Space Functions in A)	$\mathcal{H} \times \cdots \times \mathcal{H}$
Σ	Covariance of Good Data, $\mathbf{E}_{X \sim \mathcal{P}_g \phi} [X \otimes X]$	$\mathcal{H} \otimes \mathcal{H}$
Γ	Sub-Gaussian Proxy for good data (see § 2.3)	$\mathcal{H} \otimes \mathcal{H}$
K_A	Kernel Matrix s.t. $K_{ij} = k(\mathbf{x}_i, \mathbf{x}_j)$ for $i, j \in A$	$\mathbb{R}^{n \times n}$
P	Set of vectors for good data	$\{\mathcal{X}\}$
Q	Set of vectors for bad data	$\{\mathcal{X}\}$
X	All Data, $P \cup Q$	$\{\mathcal{X}\}$
TP	<i>True Positives</i> , $S^{(t)} \cap P$	$\{\mathcal{X}\}$
FP	<i>False Positives</i> , $S^{(t)} \cap Q$	$\{\mathcal{X}\}$
TN	<i>True Negatives</i> , $(X \setminus S^{(t)}) \cap Q$	$\{\mathcal{X}\}$
FN	<i>False Negatives</i> , $(X \setminus S^{(t)}) \cap P$	$\{\mathcal{X}\}$
P_k	$\max_{\mathbf{x} \in P} \sqrt{k(\mathbf{x}_i, \mathbf{x}_i)}$	\mathbb{R}_+
Q_k	$\max_{\mathbf{x} \in Q} \sqrt{k(\mathbf{x}_i, \mathbf{x}_i)}$	\mathbb{R}_+
f_{TP}^*	$\arg \min_{f \in \mathcal{H}} \frac{1}{n(1-\epsilon)} \sum_{i \in TP} (f(\mathbf{x}_i) - f^*(\mathbf{x}_i) - \xi_i)^2 + \tau \ f\ _{\mathcal{H}}^2$	\mathcal{H}
\hat{f}_{TP}^*	$\arg \min_{f \in \mathcal{H}} \frac{1}{n(1-\epsilon)} \sum_{i \in TP} (f(\mathbf{x}_i) - f^*(\mathbf{x}_i))^2 + \tau \ f\ _{\mathcal{H}}^2$	\mathcal{H}
$\hat{\Sigma}_{TP}$	$\frac{1}{n(1-\epsilon)} \sum_{i \in TP} \phi(\mathbf{x}_i) \otimes \phi(\mathbf{x}_i)$	$\mathcal{H} \otimes \mathcal{H}$
